

ABSTRACT

1 An apparatus and method is discussed for characterizing a fluid sample downhole of
2 aliphatic hydrocarbon compounds, aromatic hydrocarbon compound, or connate mud
3 filtrates containing carbon-13 isotopes using an enhanced nuclear magnetic resonance
4 (NMR) signal on a measurement-while-drilling device. To enhance the carbon-13 NMR
5 signal these nuclei are being hyperpolarized. Either the Overhauser Effect (OE) or the
6 Nuclear Overhauser Effect or optical pumping and the Spin Polarization Induced Nuclear
7 Overhauser Effect (SPINOE) can serve as a mechanism for hyperpolarization of the
8 carbon-13 nuclei.
